## The NASA STI Program Office ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.
- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

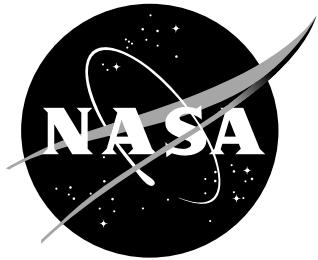

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.
- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that complement the STI Program Office's diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program Office, see the following:

- Access the NASA STI Program Home Page at <http://www.sti.nasa.gov>
- E-mail your question via the Internet to [help@sti.nasa.gov](mailto:help@sti.nasa.gov)
- Fax your question to the NASA STI Help Desk at (301) 621-0134

## **ABSTRACT**

This report presents work performed in support of NASA's Environmental Research Aircraft and Sensor Technology (ERAST) program. The primary purpose of this work was to develop and demonstrate a gust analysis method that accounts for the span-wise variation of gust velocity on unmanned aircraft characterized by high aspect ratios, low wing loading, high flexibility, and low airspeeds. The main focus of the work was therefore to perform a two-dimensional Power Spectrum Density (PSD) analysis of the Alliance 1 Proof-of-Concept Unmanned Aircraft. Suitable structural and aeroelastic Finite Element Models (FEM) were developed. One- and two-dimensional PSD gust analyses of the Alliance 1 were performed. For further validation and comparison, a two-dimensional PSD gust analysis was performed on a simple example problem, and a one-dimensional discrete gust analysis was performed on the Alliance 1. This report describes this process, shows the relevant comparisons between analytical methods, and discusses the physical meanings of the results.

## **INTRODUCTION**

This report presents the work performed by Lockheed Martin's Langley Program Office in support of NASA's Environmental Research Aircraft and Sensor Technology (ERAST) program. The primary purpose of this work was to develop and demonstrate a gust analysis method that accounts for the span-wise variation of gust velocity. The evaluation of span-wise variation of gust velocity is important for these unmanned ERAST aircraft because they are characterized by high aspect ratios and low wing loading, are very flexible, and fly at low airspeeds. In the past, the gust response of these aircraft has been mainly investigated using the Pratt-Walker formula<sup>1</sup> that is derived from a discrete gust approach. However, the Pratt-Walker formula does not capture the effects of structural flexibility and the span-wise variation of gust velocity. The main focus of the work was therefore to perform a two-dimensional Power Spectrum Density (PSD) analysis of the Alliance 1 Proof-of-Concept Unmanned Aircraft. As of this writing, none of the aircraft described in this report have been constructed. They are concepts represented by analytical models.

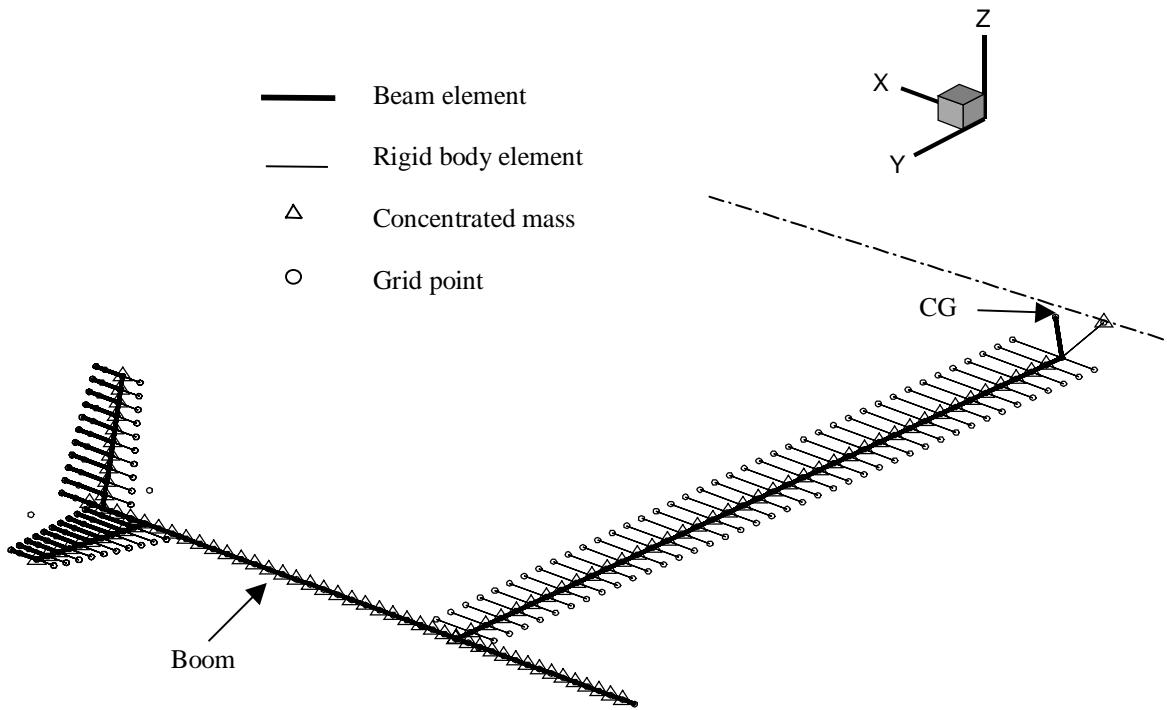

The process first involved the development of suitable structural and aeroelastic Finite Element Models (FEM). This was followed by development of a one-dimensional PSD gust analysis, and then the two-dimensional PSD analysis of the Alliance 1. For further validation and comparison, two additional analyses were performed. A two-dimensional PSD gust analysis was performed on a simple MSC/NASTRAN<sup>2</sup> example problem. This served as a basis for comparison because an independent two-dimensional analysis had previously been performed on this analytical model. Finally, a one-dimensional discrete gust analysis was performed on the Alliance 1. This report describes this process, shows the relevant comparisons between analytical methods, and discusses the physical meanings of the results and comparisons.

# 1 FINITE ELEMENT MODELS OF THE ALLIANCE 1 PROOF-OF-CONCEPT UNMANNED AIRCRAFT STRUCTURE

## 1.1 Introduction

The Alliance 1 structural FEM used in this work was derived from a semi-span FEM originally developed by Scaled Composites Inc<sup>3</sup>. The Scaled Composites' FEM contained chord-wise grids on the lifting surfaces that were joined to the elastic axis grids by very stiff beam elements. By replacing the stiff beams with MSC/NASTRAN<sup>4</sup> rigid elements, the number of degrees-of-freedom was substantially reduced. In addition, the chord-wise incidence angle of the wing was eliminated as it was not needed for the linear aeroelastic model. Consequently, the plane of wing grid points has dihedral angle but no angle of incidence. On the horizontal and vertical tails, additional grids were introduced at 80% chord along the full span of these surfaces to represent the hinge lines of the control surfaces. The new semi-span model was compared to the Scaled Composites' FEM by checking the mass properties, natural frequencies, and mode shapes, which all matched. Later, in the gust analyses, the mass was changed to represent a desired fuel condition.

Figure 1.1 shows the resulting MSC/NASTRAN semi-span model which was used in the one-dimensional PSD gust analysis. A corresponding full-span model possessing identical stiffness and mass properties was used in the two-dimensional PSD gust analysis. The FEM input files are included in the appendices and are referred to as appropriate throughout the report.

**Figure 1.1: Semi-span structural FEM of the Alliance 1 Aircraft showing beam elements, rigid body elements, grid points and concentrated masses.**

The stiffness properties are contained in beam elements (heavy lines in Figure 1.1) which run along the elastic axis of the wings, booms, horizontal tails and vertical tails. Very stiff beam elements also connect

the tail elastic axes with grid points at 80% chord and at the trailing edges. All of the model mass is contained in the concentrated masses which are offset from the grids that lie along the elastic axes. Rigid body elements connect the grid points at the leading and trailing edges of the wing, and leading edges of the tails. The purpose of the grids connected to the main structure by the rigid body elements is to provide mode shape displacements so that motion can be splined onto the aerodynamic surfaces.

In order to aid the model verification process, a number of grid points were added to the horizontal and vertical tails. On each tail surface, coincident grids were positioned on the existing grid locations at the leading edge, elastic axis, and trailing edge. However, the displacements of these extra grids are presented in the local tail coordinate systems.

## 1.2 Aeroelastic Models

As with the structural model, the aeroelastic model started with a semi-span model originally provided by Scaled Composites Inc. In the present work, both semi-span and full-span aeroelastic models were developed, with the full-span containing a left half which is symmetric to the right half, but identical in terms of properties. Following are descriptions of the coordinate systems and aerodynamic paneling for the semi-span aeroelastic model.

### 1.2.1 *Coordinate Systems:*

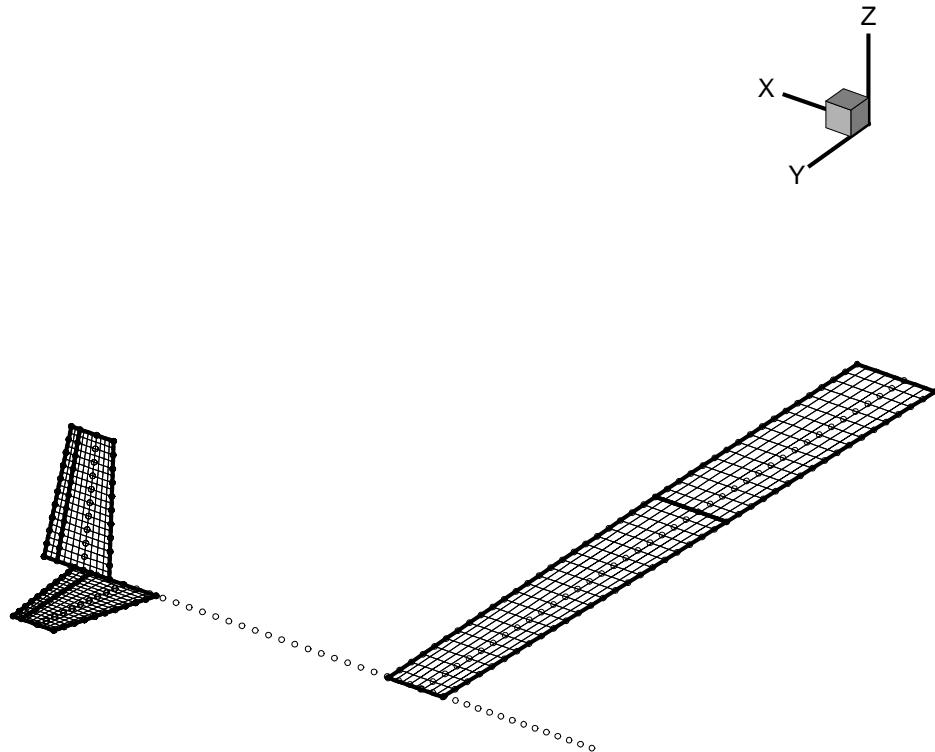

Coordinate systems used for structural modeling and aerodynamic paneling include:

- a) Basic coordinate system (coordinate system 0) which is used to define locations of all structural grid points. The origin for this coordinate system is on the fuselage centerline ahead of the airplane with the x-axis directed aft and the y-axis out the right side. The basic coordinate system also serves as a Cartesian aerodynamic coordinate system. Aerodynamic flow is in the positive x direction and the x axis of every aerodynamic element is parallel to the flow.
- b) Reference axis system for stability derivatives (coordinate system 12) has its origin at grid 101 on the airplane centerline with x-axis directed forward and z-axis downward.
- c) Local coordinate systems which place their (x, y) axes in the plane of the horizontal and vertical tail surfaces (coordinate system 5 for horizontal tail and 6 for the vertical tail).
- d) Coordinate systems whose y-axes define the hinge lines of the aerodynamic panels that constitute the control surfaces on the vertical and horizontal tails.
- e) Element coordinate systems for aerodynamic macro elements (CAERO1 entry of Reference 1) which govern the sequence numbering of the doublet lattice aerodynamic boxes. There are a total of 6 coordinate systems of this type, with two on the right-side wing (origins at grids 101 and 118), two on the non-movable sections of the horizontal and vertical tails (with origins at grids 1301 and 1411 respectively), and two on the control surfaces of the horizontal and vertical tails (grids 2501 and 2611 respectively).

## 1.3 Aerodynamic Paneling

Figure 1.2 shows the structural grids and aerodynamic panels used in the semi-span model. The main wing was divided into inboard and outboard panels, with the break occurring at a span station of 223.5

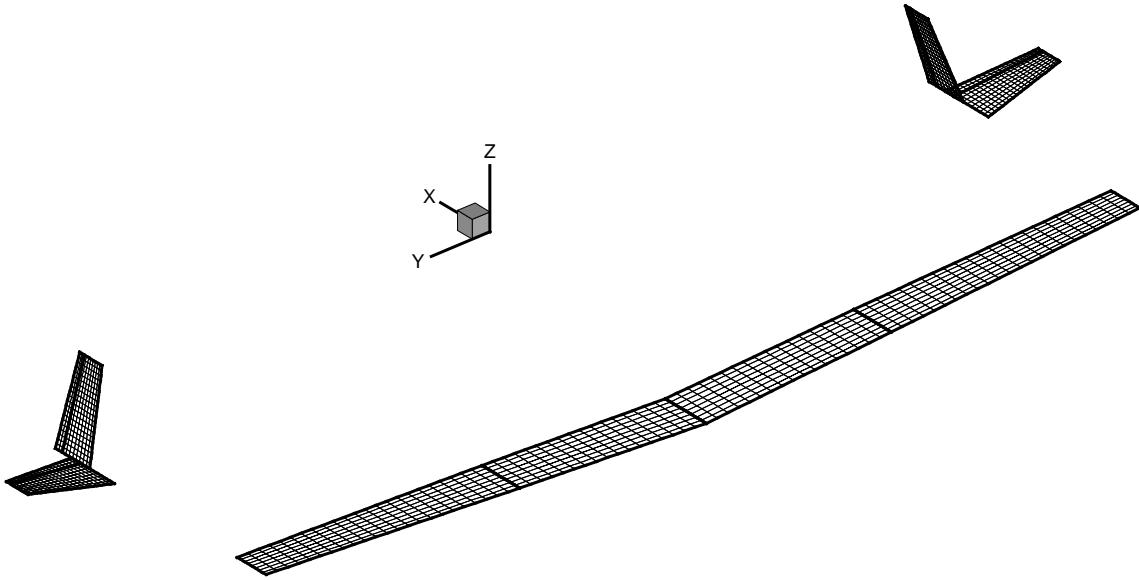

inches. The horizontal and vertical tails each are modeled with two panel elements. In both cases, the first panel extends from the leading edge of the lifting surface up to the hinge line, and the second panel continues from the hinge line to the surface trailing edge.

**Figure 1.2: Semi-span aeroelastic FEM showing structural grids and aerodynamic panels and boxes.**

Figure 1.3 gives an overview of the full-span aerodynamic model, and Figure 1.4 shows the aerodynamic box number pattern. The inboard wing panels have 8 chord-wise boxes and 17 span-wise boxes, while the outboard wing panels have 8 chord-wise boxes and 23 span-wise boxes. The panel box identification labels begin with 10001 for the right inboard wing and 20001 for the right outboard wing and so on. For the right side horizontal tail, the first panel begins at the leading edge and has 8 chord-wise boxes up to the hinge line of the control surface at 80% chord. The box labels begin with label 30001. The control surface aerodynamic panel has 2 chord-wise boxes and begins with label 31001. Both horizontal tail aerodynamic panels have 20 span-wise boxes. On the right side vertical tail box 40001 begins at the tip leading edge and extends to the 80% chord hinge line. This panel has 8 chord-wise boxes and 20 span-wise boxes. The panel extending from the hinge line to the trailing edge has 2 chord-wise boxes, 20 span-wise boxes and begins with label 41001. The left side aerodynamic panels and boxes have a similar numbering scheme as shown in the figure.

The modal displacements of aerodynamic boxes are related to displacements of the structural grids by a surface splining technique. Doublet Lattice aerodynamic modeling does not allow for angle of incidence, camber or twist in lifting surface panel definition. Therefore, the present model does not include such geometry. While these effects are disregarded in lifting surface flutter methods, they could, in the real world, affect aeroelastic trim and gust loading.

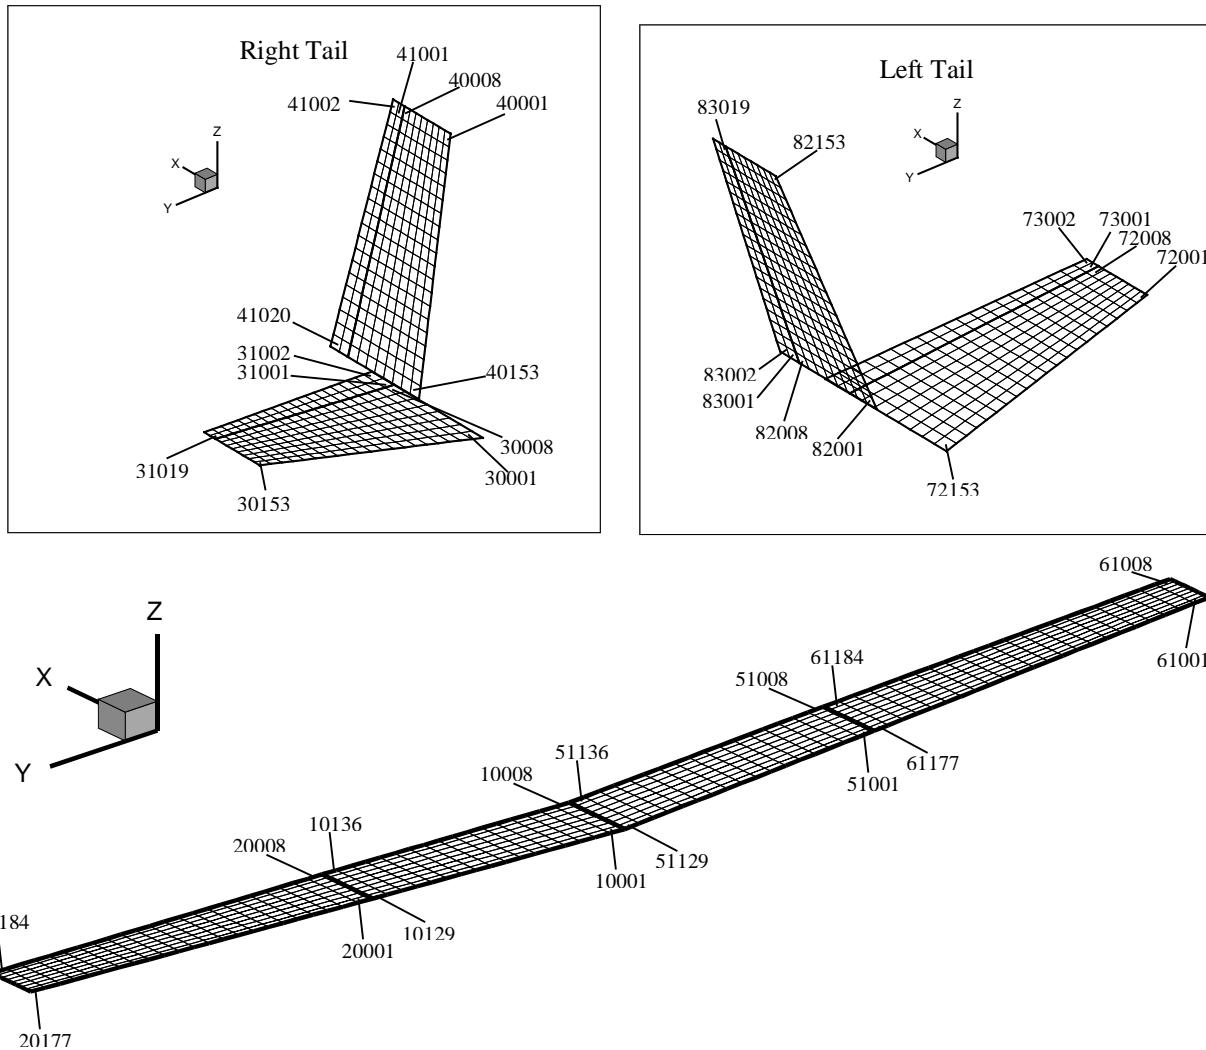

**Figure 1.3: Overview of full-span aerodynamic model.**

#### 1.4 Verification of Semi-Span Aeroelastic Model

In order to demonstrate that the model was well conditioned and that it would be free from flutter at conditions of interest for gust analysis, trim and flutter analyses were conducted as described further below. Appendix A contains the input FEM file for trim, and Appendix B for flutter. Table 1-1 gives the weight, center of gravity (CG) location, and first 10 symmetric modal frequencies for the semi-span model used in the verification process. Symmetric modal frequencies (for the semi-span model) were produced by applying symmetric boundary conditions at the wing root.

A flutter solution was obtained using the PK method. The input conditions were at Mach 0.0, sea-level, velocity variation from 176 in./sec. to 7040 in./sec., and use of the 10 lowest-frequency symmetric modes. Inspection of the aerodynamic panel displacements in the rigid body pitch mode confirmed proper surface spline interpolation from the structural to the aerodynamic grid points. The model is flutter free for the configuration and conditions analyzed. The MSC/NASTRAN output file containing detailed modal data and flutter results can be produced by the input file in Appendix B. The differential pressure coefficient for the right wing and right horizontal tail at trim conditions are shown in figures 1.5 and 1.6, respectively.

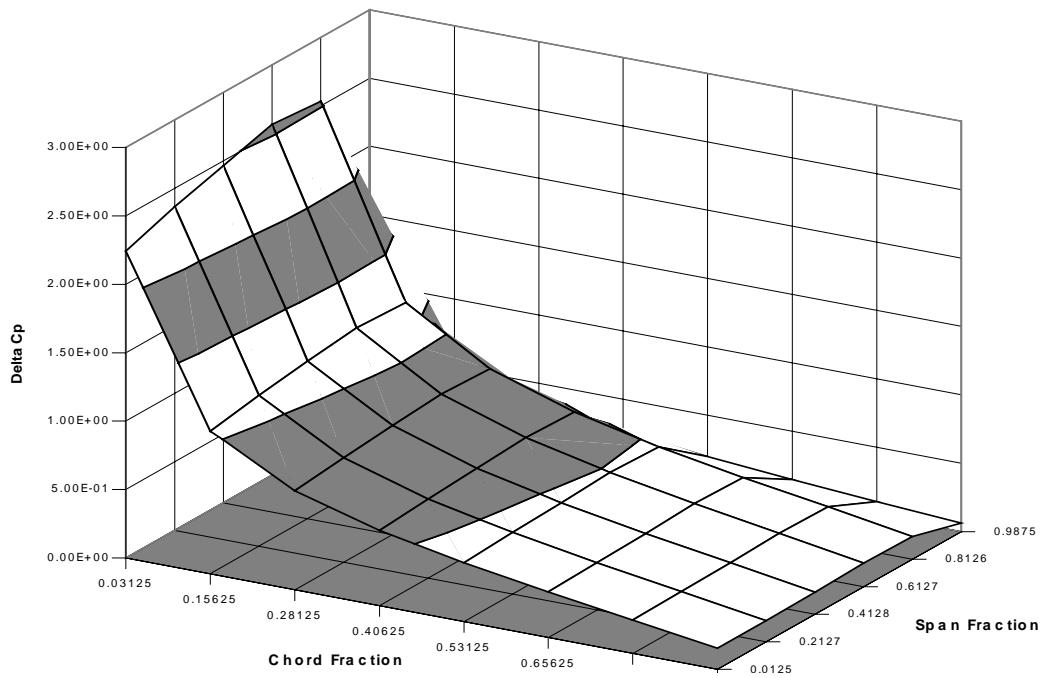

**Figure 1.4: Full-span aerodynamic FEM showing aerodynamic panels and box number pattern.**

## 2 ONE-DIMENSIONAL VON KARMAN PSD GUST ANALYSIS

The purpose of this phase of the work was to perform dynamic analysis of the semi-span Alliance 1 aircraft subjected to a one-dimensional random gust load. The power spectral density (PSD) of the gust load is represented by the von Karman model<sup>5</sup>. The finite element program MSC/NASTRAN<sup>4</sup> was used for the entire analysis. The input data requirements were generated for a single set of flight conditions. Symmetry conditions were imposed on grid points located on the plane of symmetry and 32 normal modes spanning a frequency band up to 60 Hertz were included in the analysis. PSD of different response quantities such as accelerations, moments and torques at critical grid points of the structures are generated and plotted for a range of frequencies that covers the elastic modes of vibration. The semi-span finite element model is shown in Figure 2.1 with some of the critical grid points labeled for identification. Appendix C contains the complete MSC/NASTRAN data deck.

**Figure 2.1: Semi-span structural FEM of the Alliance 1 Aircraft showing critical grid points.**

### 2.1 Flight Conditions

The MSC NASTRAN Finite-Element model of the aeroelastic semi-span Alliance 1 Proof of Concept aircraft model was described in Section 1. Data records required to support a random dynamic loads analysis using the von Karman gust spectrum<sup>5</sup> were inserted into the MSC/NASTRAN Bulk Data deck. Analyses were conducted at the following flight conditions:

Altitude:	1000.0 ft
True Air Speed:	98.3 ft/sec
Dynamic pressure:	0.077444 psi
Mach Number:	0.09
Fuel Loading Condition:	333.9 lb. (total full model fuel weight)

## 2.2 Response Quantities Investigated

The PSD of the loads and accelerations at different grid points of interest were investigated. Loads were calculated at grid points 101(wing root), 140 (on the wing elastic axis near the tail boom), and 217 (on the tail boom just aft the wing elastic axis). The loads investigated are:

- Plane 1 bending moment, M1, which is the moment about the element's vertical axis (wing or boom in-plane bending moment).
- Plane 2 bending moment, M2, which is the moment about the element's horizontal axis (vertical bending moment).
- Plane 1 shear force, V1, which is the web shear force in the direction of the element's horizontal axis (in-plane shear).
- Plane 2 shear force, V2, which is the web shear force in the direction of element's vertical axis (vertical shear).
- Total web torque T.

The PSDs of accelerations were calculated at grid points 95 (the center of gravity of the corresponding full airplane), 140, and 217. The accelerations investigated are:

- Transnational acceleration in the global x-direction, A1, which is in the direction of the flow.
- Transnational acceleration in the global z-direction, A2, which is in the vertical direction.
- Rotational acceleration about the span-wise axis, A5, which is the pitching acceleration.

## 2.3 MSC/NASTRAN Input and Output

The desired total fuel weight was entered into the data deck distributed among 7 grid points. A normal modes analysis (Solution 103) was performed to obtain the new weight and center-of-gravity (CG) location and to determine the number of modes within a frequency band of 60 Hertz for symmetric boundary conditions on the vehicle centerline. The imposed boundary conditions permit vehicle fore-and-aft motion, vertical translation, and pitch rotation for the plane-of-symmetry grids. Since one of the desired output quantities is the acceleration at the center of gravity of the airplane (CG), an additional grid point was added to the model at the new CG position. This grid was given the identification label of 95 and connected to Grid 101 on the vehicle centerline with a relatively stiff beam element (see Figure 2.1).

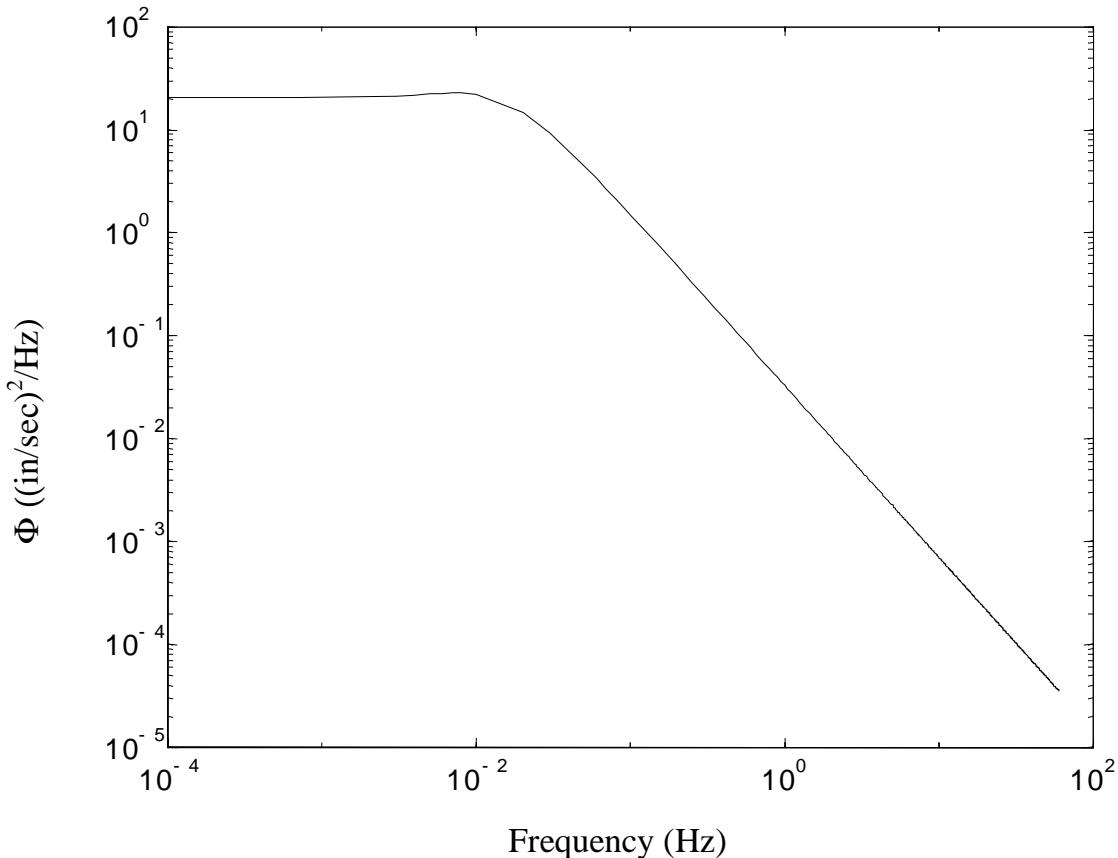

The von Karman PSD of the gust is defined on the TABRNDG Bulk data deck input record. User input requirements were:

L (Scale of turbulence):	1000.0 ft
WG (Root-mean-square gust velocity):	1.0 in/sec

Additional input cards required to support the analysis were:

DAREA	Defines scale factors for dynamic loads set
FREQ1	Defines frequencies used in solution of frequency response problems
GUST	Defines a stationary vertical gust
RANDPS	Defines load set PSD factors
RLOAD1	Defines form of the frequency-dependent dynamic load
TABLED1	Defines frequency band for generation of dynamic loads
PARAM	inputs required included:
LMODE	Specifies the number of lowest normal mode to include
MACH	MACH number used to compute aerodynamic matrices
Q	Specifies the dynamic pressure

To obtain a listing of the von Karman spectrum an extra point was defined using the EPOINT Bulk Data entry in conjunction with DMIG. This procedure, which is described in the MSC/NASTRAN Aeroelastic User's Guide<sup>4</sup>, positions an extra point into an unused region of the stiffness matrix which provides a way to calculate the spectrum of the input gust. The PSD of the von Karman gust is shown in Figure 2.2. This plot is generated from EPOINT 9990. It is worth mentioning that while the equation in the MSC/NASTRAN Aeroelastic User's Guide<sup>2</sup> for the von Karman equation is incorrect, the actual analysis in the code is correct.

**Figure 2.2: Power spectral density function of the von Karman gust.**

## 2.4 Results and Discussion of the One-Dimensional Analysis

A summery of the weight and the location of the CG of the semi-span model with respect to the basic coordinate system is given in Table 2-1.

Table 2-2 shows the lowest 32 natural frequencies of the structure for a for symmetric boundary conditions on the vehicle plane of symmetry. The first 3 modes are rigid body modes (plunge, pitch, and fore-aft.). The elastic mode shapes are plotted in Figure 2.3.

**Table 2-1: Weight summaries for the half-span model with respect to the basic coordinate system.**

Weight (lb)	X-C.G. (in)	Y-C.G. (in)	Z-C.G. (in)
1047.7	160.9	207.2	77.1

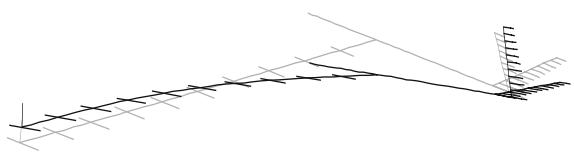

**Table 2-2: Natural frequencies of the modes included in the one-dimensional PSD gust analysis.**

Mode #	Frequency (Hz)						
1	0.000	9	4.117	17	15.340	25	38.740
2	0.000	10	6.115	18	16.717	26	40.058
3	0.000	11	6.749	19	21.315	27	43.874
4	0.380	12	8.314	20	23.917	28	44.948
5	0.813	13	9.271	21	26.451	29	50.464
6	1.290	14	10.870	22	31.500	30	51.756
7	2.036	15	12.840	23	31.927	31	55.838
8	2.201	16	14.599	24	36.936	32	59.570

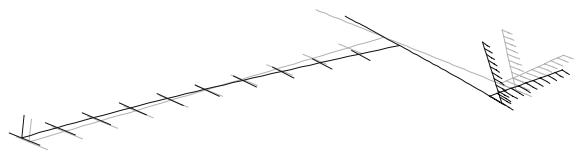

The excitation frequencies used in the frequency response solution ranged from 0.001 Hz to 60.0 Hz in three bands specified on FREQ1 data records. Figure 2.2 shows the Power Spectral Density of the von Karman gust over this total frequency band.

PSD of the bending moment in the vertical plane,  $M_1$ , for grid point 101 is plotted in Figure 2.4. PSD of  $M_2$ ,  $V_1$ ,  $V_2$ , and  $T$  for the same grid point are shown in Figure 2.5-Figure 2.8, respectively. The largest response for bending moment,  $M_2$ , occurs at a frequency of about 0.4 Hz, which is the frequency of the first bending mode. A smaller peak of  $M_2$  response occurs at a frequency of 2 Hz. It can be seen from figure 6 that this frequency is the natural frequency of the second bending mode of the wing. Higher modes do not appear to influence the bending moment response. Moment  $M_1$  has a large and sharp peak at about 2 Hz with multiple smaller peaks at lower frequencies. The PSD of the torque at this point has peaks at 0.8 Hz and 1.3 Hz, which are the natural frequencies of the first two torsional modes of the wing.

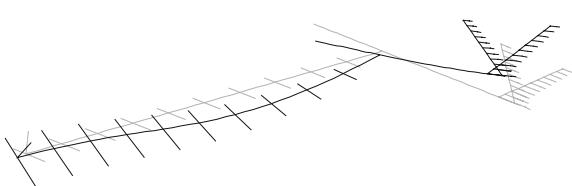

Results similar to Figure 2.5-Figure 2.8 are shown in Figure 2.9-Figure 2.13 for grid point 140. Results are also shown in Figure 2.14-Figure 2.18 for grid point 217. The peaks of the different loads for each of the points studied vary depending on the location and type of quantity studied.

The PSDs of the acceleration components of the center of gravity in the flow direction,  $A_1$ , the vertical direction,  $A_3$ , and about the pitching axis,  $A_5$ , are shown in Figure 2.19-Figure 2.21, respectively. As expected, the highest acceleration magnitude is in the vertical direction. Additionally, the translational accelerations  $A_1$  and  $A_3$ , are affected by both bending and twisting modes. This is mainly because the center of gravity is offset horizontally from the elastic axis of the wing. The angular acceleration,  $A_5$ , on the other hand, peaks mainly at the natural frequencies of the torsional modes. Similarly, accelerations  $A_1$ ,  $A_3$ , and  $A_5$  for point 140 are shown in Figure 2.22-Figure 2.24, and for point 217 in Figure 2.25-Figure 2.27.

Additional requested output quantities were the root mean square value ( $\bar{A}$ ) of the responses and the expected rate of zero crossings with positive slope ( $N_0$ ). These statistical quantities are important for failure and fatigue analyses. These quantities are summarized in Table 2-3.

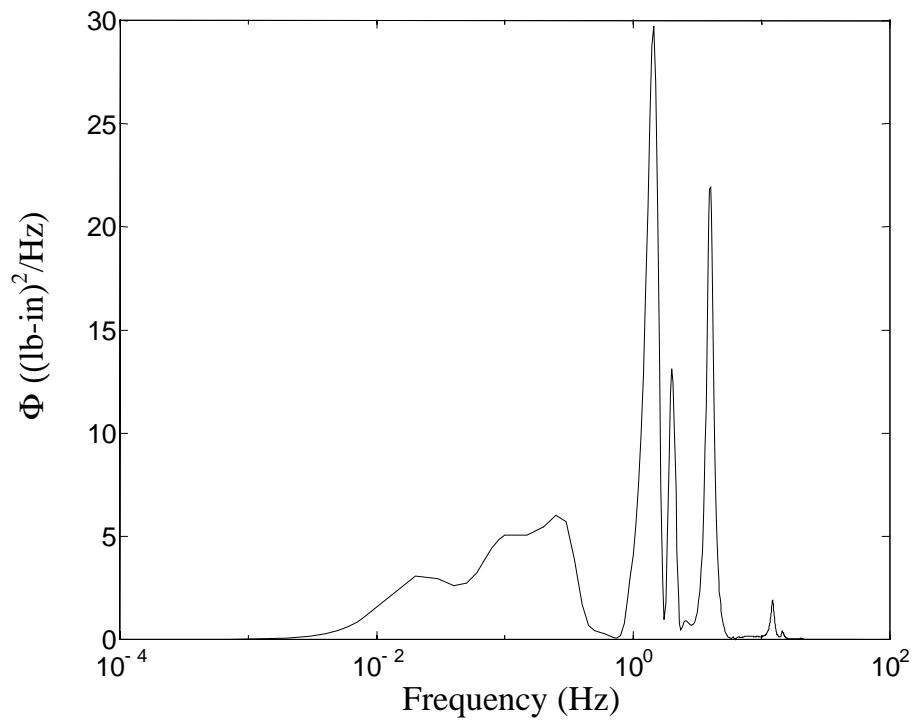

In order to ascertain that the solutions were converged with respect to the frequency range analyzed and the number of modes used in the analysis, the number of modes used was increased from 20 to 32 with no significant changes in loads. This includes the response RMS values shown in Table 2-3. Also, note that in Figure 2.4-Figure 2.18, no significant loads exist above 20 Hertz, whereas flexible modes and excitation loads exist at frequencies three times greater.

**Table 2-3: Summary of the probability parameters for response quantities.**

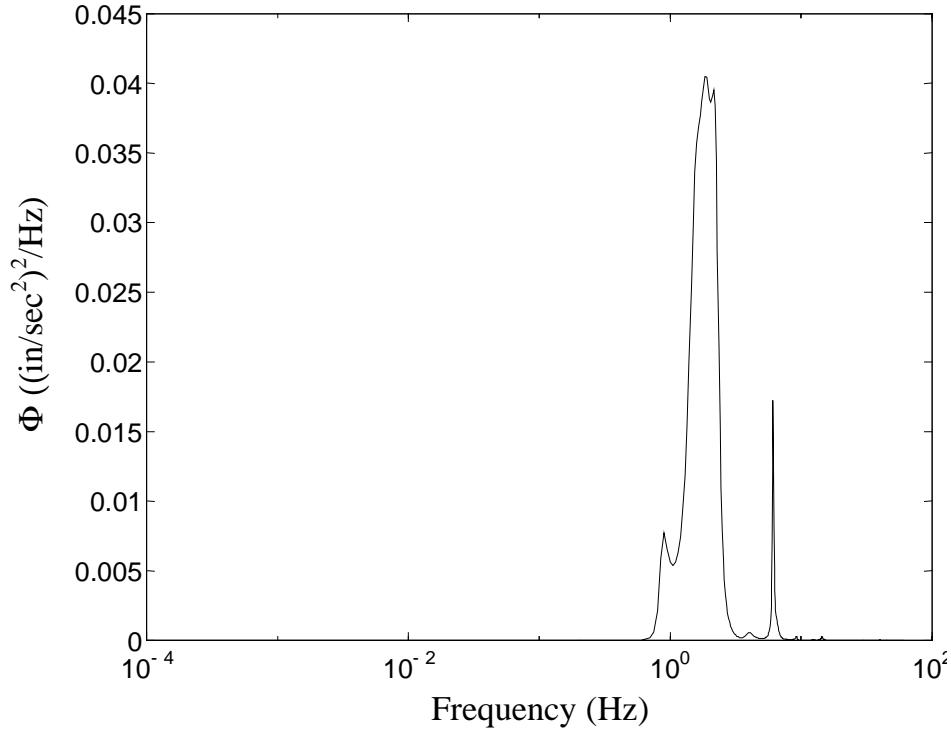

Point number	Type of response	$\bar{A}$	$N_0$ (Hz)
101	$M_1$	92.91 (lb-in)	1.94
	$M_2$	153.4 (lb-in)	1.473
	$V_1$	0.375 (lb)	2.450
	$V_2$	0.952 (lb)	2.217
	T	44.29 (lb-in)	2.316
140	$M_1$	51.10 (lb-in)	1.988
	$M_2$	8.080 (lb-in)	2.528

### 3 TWO-DIMENSIONAL PSD GUST ANALYSIS

#### 3.1 Introduction

This section deals with the two dimensional PSD gust analysis which was the central issue addressed in the entire study. All of the other work was done in order to develop and validate the two-dimensional process, or to correlate and compare the two-dimensional results with one-dimensional results. The gust load was represented by the cross spectral density between correlation strips spanning the airplane and parallel to the flight direction. The full-span structural and aeroelastic FEMs described in Section 1 were used for the analysis. As the capability of MSC/NASTRAN is limited to aerodynamic analysis under uniform (one dimensional) gust loads, Direct Matrix Abstraction Program (DMAP)<sup>6</sup> alters were introduced in the program to extract the frequency response functions (FRF) of the response from each of the correlation strips. One hundred and sixty (160) correlation strips were used, covering 1440 aerodynamic boxes. Programs written in MATLAB<sup>7</sup> were used to generate the cross spectral matrices and perform the post processing of the data generated by MSC/NASTRAN. The input data requirements were generated for a single set of flight conditions. Using no restraints (free-free boundary conditions), 64 normal modes spanning a frequency band up to 60 Hertz were computed and included in the analysis. PSD of different response quantities such as accelerations, moments and torques at critical grid points of the structures are generated and plotted for a range of frequencies that covers the elastic modes of vibration. The flight conditions and response quantities investigated are identical to those in the one-dimensional analysis.

#### 3.2 MSC/NASTRAN Input and Output

The desired total fuel weight was entered into the data deck distributed among 14 grid stations. A normal modes analysis (Solution 103) was performed to obtain the weight and center-of-gravity (CG) location and to determine the number of modes within a frequency band of 60 Hertz. For the full-span case, the CG is at the centerline, and both symmetric and anti-symmetric mode shapes are involved. Appendix D contains complete listings of the MSC/NASTRAN files used in the two-dimensional analysis.

The lifting surfaces of the airplane were represented by 1440 aerodynamic boxes used for the doublet-lattice method. Each row of aerodynamic boxes in the chord-wise direction was used to represent a correlation strip for the two dimensional gust analysis. A DMAP alter was written to calculate the frequency response functions under unit aerodynamic loads acting on the correlation strips. The DMAP alter loops through the correlation strips which are identified by direct matrix input (DMI) cards. It was necessary to run each side of the airplane separately because the version of MSC/NASTRAN used restricted the maximum number of DMI cards to 100. The input cards required for the MSC/NASTRAN analysis include:

FREQ2	Defines frequencies used in solution of the frequency response problems.
MKAERO	Defines a set of Mach numbers and reduced frequencies to be used in the generation of the frequency response function.

PARAM inputs required included:

NSTRIPRM	Specifies the number of strips to be analyzed.
LMODE	Specifies the number of lowest normal mode to include.
MACH	MACH number used to compute aerodynamic matrices.
Q	Specifies the dynamic pressure.

In the absence of experimental estimates for the structural damping as a function of frequency, a modal structural damping of 0.02 was assumed over the entire analysis band of 60 Hz.

The desired set of analysis parameters is selected by the MSC/NASTRAN Case Control inputs. These inputs include:

FREQUENCY	Selects a set of desired solution frequencies (FREQ2).
METHOD	To select the eigenvalue extraction method (EIGR).
RANDOM	Selects the power spectral density factors (RANDPS) for the uniform case.
SDAMPING	Selects the desired modal damping (TABDMP1).

A SUPORT card was used to insure that the rigid-body modes have exactly zero frequencies.

XYPRINT specifications were required to create printouts of the FRFs from each strip. The output was chosen to be in the form of a "punch file". The MATLAB programs used in the post processing can, however, read "f06" files as well.

### 3.3 MATLAB Input and Output

MATLAB programs were written to generate the gust load cross-spectral matrices at each frequency, read the FRFs generated by MSC/NASTRAN, and calculate the power and cross-spectral densities of the responses. The input lists are contained in appendix E. The user needs to run only the program called "calc\_response.m" with no input parameters. This program will call all the necessary programs to calculate the responses and their statistics. The cross-spectral density  $\phi_{12}$  of the gust loads for two correlation strips is calculated according to reference 3 using the following equation:

$$\phi_{12}(\omega) = \frac{\sigma_w^2}{\sqrt{2\pi}} \frac{2^{2/3}}{\Gamma(1/3)} \frac{L}{V} \left(\frac{1}{1.339}\right)^{8/3} \left[\frac{8}{3}(1.339)^2 \frac{\sigma^{5/3}}{z^{5/6}} K_{5/6}(z) - \frac{\sigma^{11/3}}{z^{11/6}} K_{11/6}(z)\right] \quad (3.1)$$

where:

$$z = \frac{\sigma}{1.339} \sqrt{1 + (1.339\nu)^2}, \quad (3.2)$$

$$\nu = \frac{\omega L}{V},$$

$$\sigma = \frac{s}{L},$$

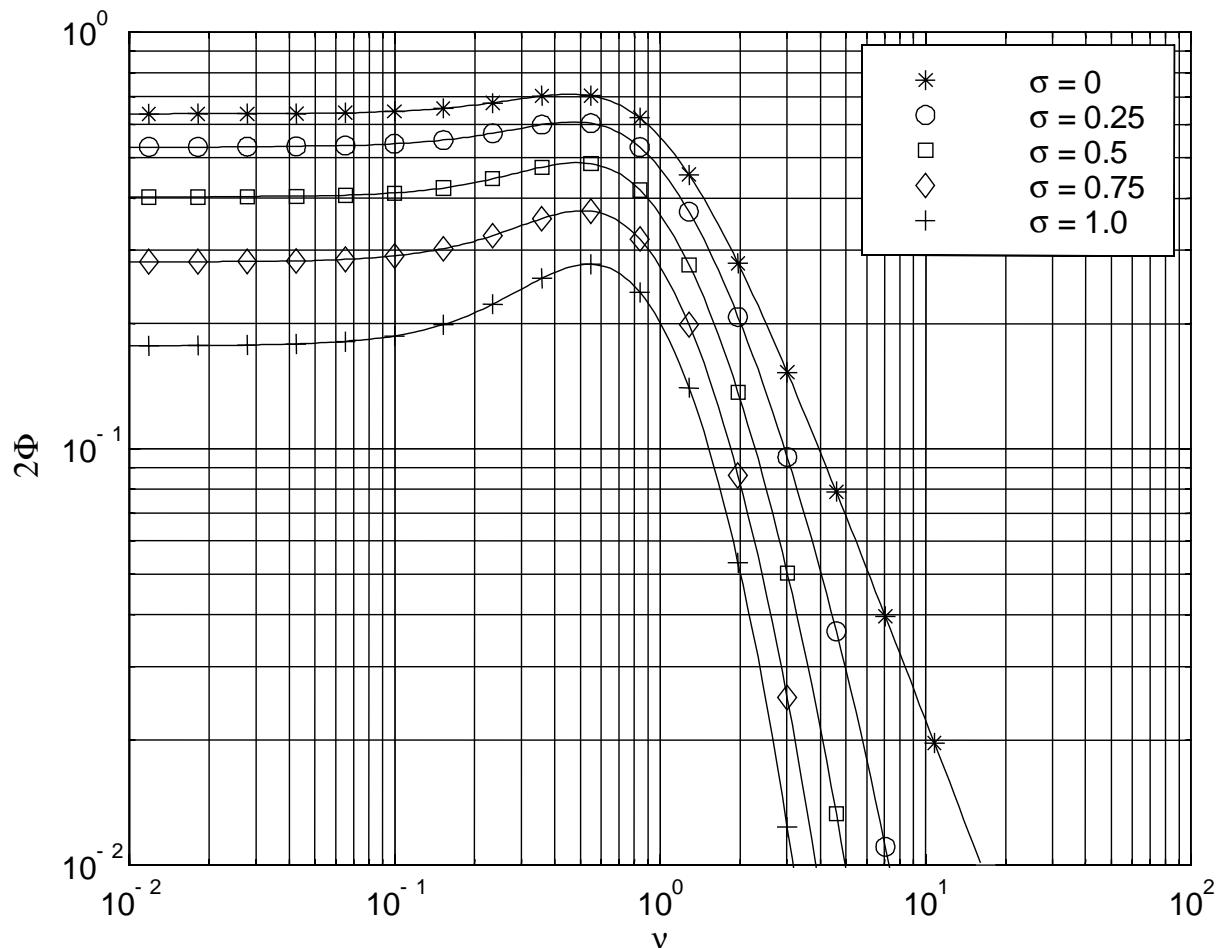

$s$  is the separation distance between the two strips,  
 $L$  is the gust scale length,

$\sigma_w$  is the rms value of the gust speed, and

$K_i$  is the modified Bessel function of the second kind of order  $i$ .

The values of these variables are entered in a data file called "case\_info.data". This file is read by the program "calc\_response.m". Other information in the "case\_info.data" file includes the name of the punch or "f06" file that has the FRF data, the number of frequency points used in the MSC/NASTRAN analysis,

the number of response quantities analyzed, and the number of correlation strips used in the analysis. A family of cross-spectral densities of the gust load is shown in Figure 3.1.

**Figure 3.1: Non-dimensional gust cross-spectral spectral density for various non-dimensional separation distances.**

The Matlab program “calc\_resp.m” generates the following output quantities in order:

- The frequency vector,
- The auto power spectral matrix whose columns are the PSD vectors for each response quantity,
- A three-dimensional array for the cross-spectral matrices,
- The root-mean-square (RMS) values of the responses,
- The expected number of positive slope zero-crossings ( $N_o$ ) of the responses.

The cross-spectral matrix of the response quantities is calculated in terms of the FRF matrix and the cross-spectral matrix of the gust load according to the following equation (reference 8):

$$[\phi_r(\omega)] = [H'(\omega)][\phi_g(\omega)][H(\omega)] \quad (4.2)$$

where  $\phi_r$  is the cross-spectral matrix of the responses,

$\phi_g$  is the spectral-spectral matrix of the gust load,

$H$  is the FRF matrix, and

$H'$  is the complex conjugate transpose of  $H$ .

### 3.4 Verification of the Procedure

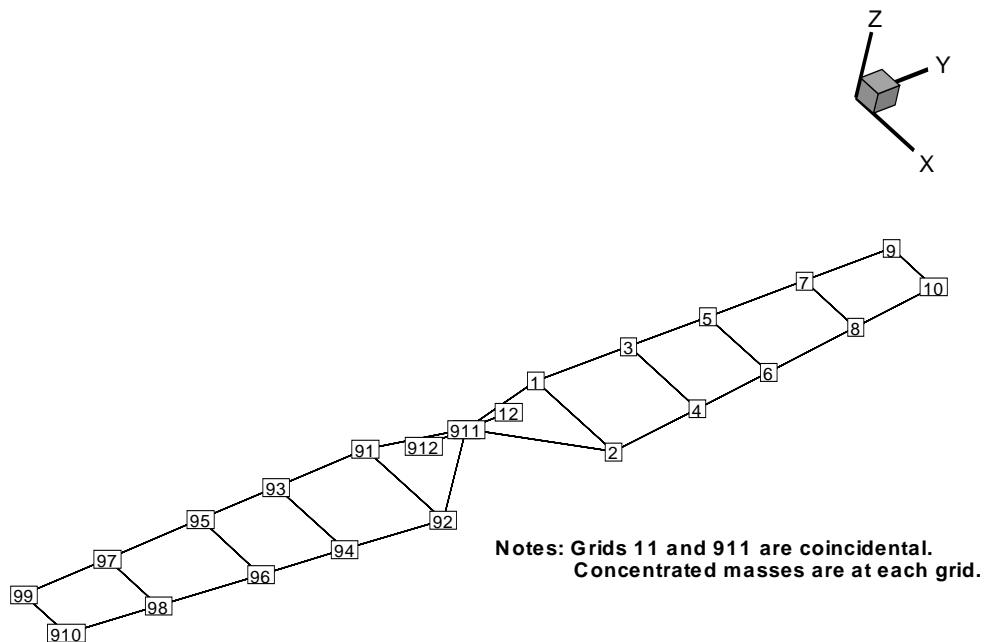

To verify the procedure used in the calculation of the non-uniform gust case, the procedure was first used to calculate the response to a uniform gust. This was done by setting the separation distances between all the strips to zero. This means that the cross-spectral density and the auto-spectral density is the same and is equal to the gust spectral density in the uniform gust case. The results of this procedure were compared to the results obtained directly from the MSC/NASTRAN uniform gust analysis. Both sets of results were identical. The figures plotted in this report for the uniform case were generated using this procedure. The results obtained directly from MSC/NASTRAN gust analysis were not plotted because they are an exact match of the results from the new procedure.

For further verification of the procedure used in this section, The present procedure was used to perform two-dimensional gust analysis on the jet transport wing used by Bisblinghoff, Ashley, and Halfman in reference 2, which is known in the literature as the BAH wing. The results of the present method are compared with the results reported by Crimaldi, Britt, and Rodden in reference 8.

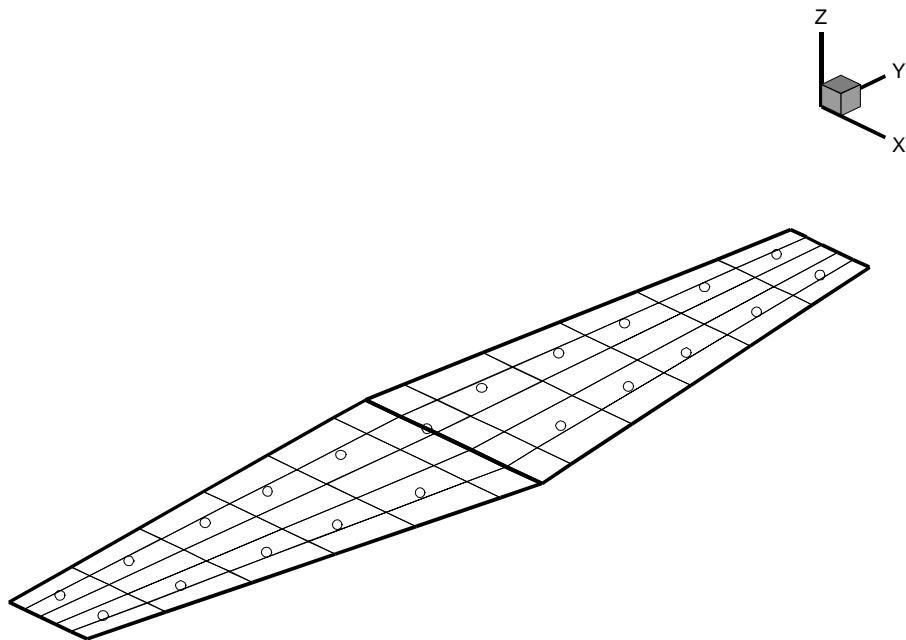

#### 3.4.1 Finite Element Model of the BAH Wing

The BAH full span wing was developed by modifying the half-span example in the MCS/NASTRAN example directory (reference 2) to produce a model similar to that used Crimaldi et al<sup>9</sup>. The right-hand wing in the example, which consisted of GENEL elements and concentrated masses, was mirrored into the left-hand side to produce the full-span wing (Figure 3.2). The GENEL elements are constrained so that the wing can only have roll, pitch, and plunge rigid body degrees of freedom. The fuselage weight was divided in half and carried by two very stiff beams 45 inches away from the center to each side. In addition, the connection point in the middle of the fuselage was broken into two co-incidental points connected by very stiff beams in order to generate the center moment from the beam stresses. This was done because structural loads cannot be recovered from GENEL elements. The structural model is shown in figure 1. The total span of the wing is 500 ft and the its total area is 162,500 in<sup>2</sup>. The root chord is 100 inches and the chord at the three-quarter span is 131.2 inches. The total weight is 83,838 lb., of which 34,800 lb. is the fuselage weight.

For the aerodynamic model (Figure 3.3), the surface of the wing was divided into a lattice of 12X5 aerodynamic boxes for use with doublet-lattice method. Those boxes are splined with the grid points of the structural model. To calculate the frequency response function under non-uniform gust loads, eleven correlation strips were formed from the rows of aerodynamic boxes spanning the whole wing. The two rows of aerodynamic boxes in the middle of the wing are lumped into one correlation strip representing the fuselage. The aerodynamic model with the grid points for the splines is shown in Figure 3.3. The MSC/NASTRAN structural and aerodynamic input file can be found in Appendix F.

**Figure 3.2: Structural model of the full-span BAH wing.**

**Figure 3.3: Aerodynamic model of the full-span BAH wing.**

### 3.4.2 Results of the BAH Two-Dimensional Gust Analysis

Normal mode analysis was performed on the structural model to verify the free vibration characteristics of the wing. The first 13 mode shapes and natural frequencies, which are the ones included in the FRF analysis, are shown in Figure 3.4. These results are in exact agreement with the natural frequencies and mode shapes reported in reference 9.

The power spectral density (PSD) of the centerline acceleration for the uniform and non-uniform gust cases is shown in Figure 3.5. This figure is also an exact match to the results of reference 9. It is noted that the response to a non-uniform gust is higher than the response to uniform gust at high frequencies. At low frequencies, however, the uniform response is higher. The root mean square value  $\bar{A}$  and the expected value of the positive slope zero-crossing rate ( $N_0$ ) of the accelerations under uniform and non-uniform gust loads were also calculated. The results of the present method are compared to the results of reference 8 in Table 3-1 and Table 3-2 for the RMS and zero crossing rates, respectively.

PSD plots for the tip acceleration and the centerline bending moment are shown in Figure 3.6 and Figure 3.7, respectively. It is noticed from the comparison of the RMS values from the current study and reference 9 that while the centerline acceleration is exactly the same (within reasonable round off error), the results of the tip acceleration and the centerline moment are different. This can be explained by the fact that the centerline acceleration is the only quantity that is calculated for the same exact point in the two studies. The tip acceleration in reference 9 is calculated for the edge of the middle aerodynamic box at the end of the wing, whereas the tip acceleration calculated here is for grid point 10, which is removed a little from the edge of the aerodynamic box. Since the objective here is to validate present method, it was used in the same way as for the Alliance 1 airplane. The comparison of the results at points other than grid points is beyond the scope of the current task.

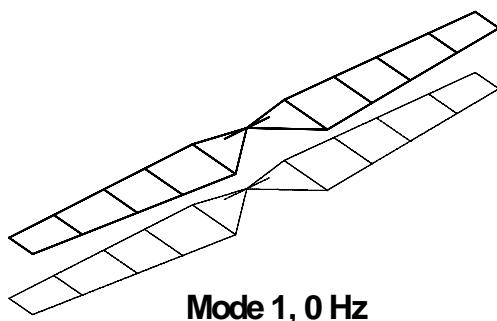

**Table 3-1: Comparison of the RMS values of the responses of the BAH wing.**

Response	Uniform		Non-uniform	
	Current	Reference 9	Current	Reference 9
Centerline acceleration	4.74 E-2	4.74 E-2	4.42 E-2	4.44 E-2
Tip acceleration	0.188	0.180	0.168	0.173
Centerline moment	2.61 E+5	2.32 E+5	2.30 E+5	2.04+E5

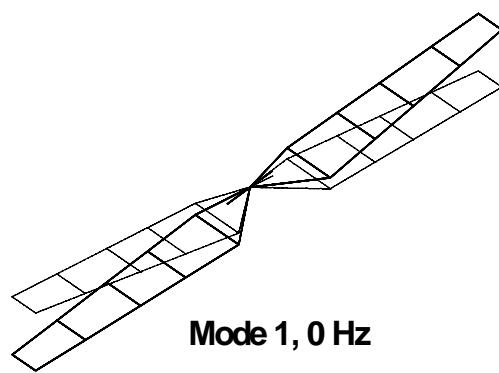

**Table 3-2: Comparison of the zero crossing rates of the responses.**

Response	Uniform		Non-uniform	
	Current	Reference 9	Current	Reference 9
Centerline acceleration	2.34	2.30	2.56	2.57
Tip acceleration	3.77	3.68	4.87	4.82
Centerline moment	2.05	2.02	2.06	1.99

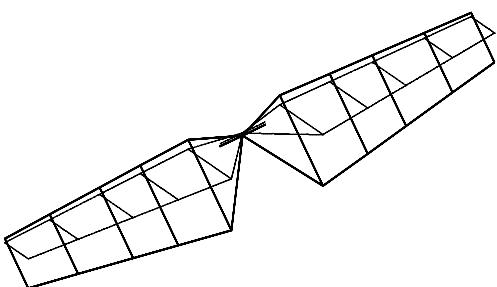

The results for the center-line moments are calculated in the current study from the internal stresses of the structural elements, similar to the method used for the Alliance 1 airplane. This was the reason for the introduction of the stiff beam elements to connect the two coincidental grid points at the center of the wing. Calculating the moments (loads in general) for points or sections on elements other than real structural elements, as in the current example, requires the calculation of integral functions of the aerodynamic loads and inertial forces at that section. This is also beyond the scope of the current task.

### 3.5 Results and Discussion of the Two-Dimensional Analysis

A summary of the weight and the location of the CG with respect to the basic coordinate system is given in Table 3-3. Table 3-4 shows the lowest 64 natural frequencies of the structure. The first 6 modes are rigid-body modes. All rigid-body and elastic mode shapes are plotted in Figure 3.8. It should be noted that the anti-symmetric and symmetric mode shapes and frequencies start to converge at higher frequencies (mode 45 and above). This numerical behavior indicates degeneracy in the finite-element model. It is unreasonable to expect sufficient fidelity to accurately predict 64 mode shapes for such a model.

The excitation frequencies used in the frequency response solution ranged from 0.01 Hz to 50.0 Hz and were specified on FREQ2 data cards, which use a logarithmic distribution for the frequencies. Figure 3.1, shown earlier, presents the cross-power spectral density over this total frequency band for several separation distances. The roll-off frequency gets smaller as the separation distance increases.

**Table 3-3: Weight summaries for the full-span model with respect to the basic coordinate system.**

Weight (lb)	X-C.G (in)	Y-C.G (in)	Z-C.G (in)
2.094578E+03	160.95	0.0	77.09

9	0.8129	25	9.2734	41	26.4514	57	50.4323
10	1.0502	26	10.8704	42	26.5199	58	50.4640
11	1.2899	27	10.9832	43	31.5077	59	51.7589
12	1.6263	28	12.0318	44	31.6183	60	52.3631
13	2.0371	29	12.8431	45	31.9269	61	55.8226
14	2.2012	30	13.8056	46	31.9337	62	55.8527
15	3.5555	31	14.6001	47	36.8595	63	59.5701
16	4.1178	32	14.8595	48	36.9357	64	59.5705

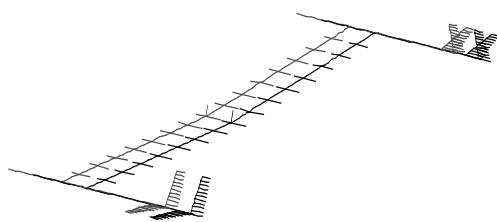

PSD of the bending moment in the vertical plane,  $M_1$ , for grid point 101 is plotted in Figure 3.9. PSD of  $M_2$ ,  $V_1$ ,  $V_2$ , and  $T$  for the same grid point are shown in Figure 3.10-Figure 3.13, respectively. The largest response for  $M_2$  occurs at a frequency of about 0.4 Hz, which is the frequency of the first elastic mode. A large response of the bending moment at this frequency, especially when the PSD of the excitation is significant in that vicinity is expected. A smaller peak of  $M_2$  response occurs at a frequency of 2 Hz which is the natural frequency of the second bending mode of the wing. Higher modes do not appear to influence the bending moment response. Moment  $M_1$  has a large and sharp peak at about 2 Hz with multiple smaller peaks at lower frequencies. This small peaks can be attributed to the coupling between the responses in planes 1 and 2. The PSD of the torque at this point has peaks at 0.4 Hz, which is the frequency of the first elastic mode, and 1.6 Hz, which are the natural frequency of the torsional mode of the wing. It is generally noticed from all these figures that the non-uniform response is higher than the uniform at low frequencies and smaller at high frequencies. This can be attributed to the fact that the high magnitude influence for the cross power spectral density of the loads is concentrated in the lower frequency range for non-uniform case and decreases at higher frequencies.

Results similar to Figure 3.9-Figure 3.13 are shown in Figure 3.14-Figure 3.18 for a grid point 140 (on the right wing elastic axis at a span fraction of 97.50%). Another set of results is also shown in Figure 3.19-Figure 3.23 for grid point 217 (at the right wing tip boom 0.373 inches forward of intersection of the wing elastic axis and the tip boom). The peaks of the different loads for each of the points studied vary depending on the location and type of response examined.

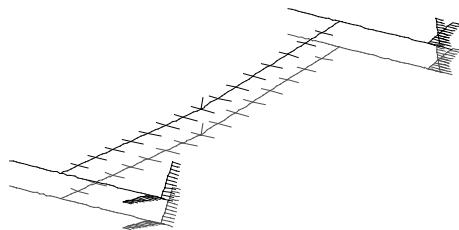

The variation along the span of the root-mean-square (RMS) values of the bending moment  $M_2$  and vertical shear force  $V_2$  are presented in Figure 3.24 and Figure 3.25, respectively. The RMS values of  $M_2$  under non-uniform gust is higher than that under uniform gust. The difference in these values is greater in the mid-span region. The RMS values of the shear force  $V_2$ , on the other hand, are closer to each other near mid-span, with the response to a non-uniform gust being greater for some region and smaller in another.

**Figure 3.24: Span-wise variation of the RMS value of moment  $M_2$ .**

The PSDs of the acceleration components of the center of gravity (point 95) in the flow direction,  $A_1$ , the vertical direction,  $A_3$ , and about the pitching axis,  $A_5$ , are shown in Figure 3.26-Figure 3.28, respectively. As expected, the highest acceleration magnitude is in the vertical direction. Additionally, the translational accelerations  $A_1$  and  $A_3$ , are affected by both bending and twisting modes. This is mainly because the center of gravity is removed from the elastic axis of the wing. The angular acceleration,  $A_5$ , on the other hand peaks mainly at the natural frequencies of the torsion modes. Accelerations  $A_1$ ,  $A_2$ , and  $A_5$  for point 140 are shown in Figure 3.29-Figure 3.31, and for point 217 in Figure 3.32-Figure 3.34.

Additional output quantities were the root-mean-square value of the responses and the expected number of zero crossings with positive slope per unit time. Table 3-5 presents a comparison of these quantities for the non-uniform and uniform gusts.

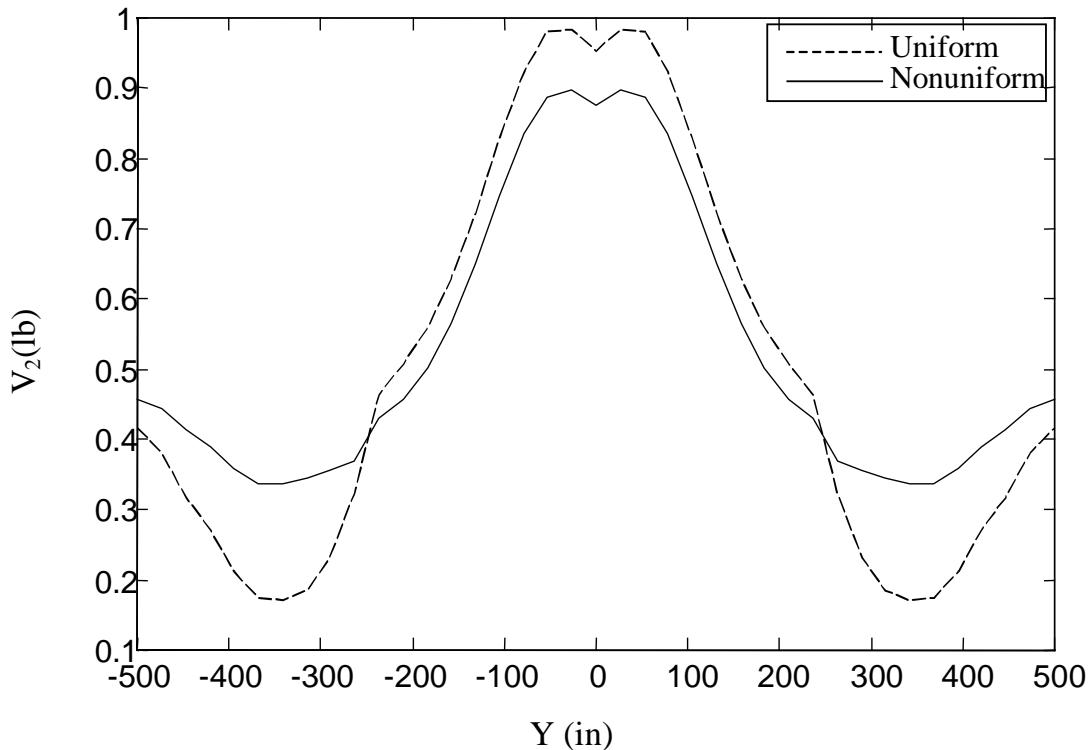

In order to ascertain that the solutions were converged with respect to the frequency range analyzed and the number of modes used in the analysis, the number of modes used was increased from 50 to 64 with no significant changes in loads. This includes the response RMS values shown in Table 3-5. Also, note that in Figure 3.9-Figure 3.23, no significant loads exist above 20 Hertz in spite of the fact that flexible modes and excitation loads exist at frequencies three times greater. Another point to be addressed here is the size of the aerodynamic model. The current model has 1440 aerodynamic boxes with 160 strips. This case was also studied using a smaller model of 720 aerodynamic boxes and 80 correlation strips. The results from the smaller model were significantly different from those of the larger model, with difference in excess of 20% for some response quantities, especially in the lower frequency range.

**Table 3-5: Summary of the probability parameters for response quantities.**

## 4 DISCRETE GUST ANALYSIS

### 4.1 Introduction

In this chapter we perform a tuned discrete gust analysis on the semi-span Alliance 1 aeroelastic/finite element model using MSC/NASTRAN's Discrete Gust Response Analysis (Reference 2) capability. The tuned discrete gust analysis presented here is based on the current (year 2000) analysis requirements of the Federal Aviation Administration Regulation (Part 25.341) airworthiness standards for transport airplanes. Due to the nature of the aircraft analyzed however, the family of gust gradient lengths used differs from that prescribed for transport aircraft.

The FAA standards have changed over last few years. In the past, a single discrete gust analysis was conducted with a gust gradient length of

$$H=12.5\bar{c} \quad (4.1)$$

where  $\bar{c}$  is the mean aerodynamic chord, and only from that analysis where the peak loads and the correlated loads assessed. Because the single calculation did not give the maximum design load, a tuned discrete gust approach was adopted. The new requirement has two alleviating factors included in load computations. The first is for high altitude aircraft that spend little time at gust-prone low altitudes and the other is a  $H^{1/6}$  factor which has an attenuating effect on the higher frequency modes.

Wing loading for the Alliance 1 is approximately 5 lbs/ft<sup>2</sup>, which is less than 1/20th of a typical transport aircraft. Typical internal structural loads due to discrete gusts for this type of light aircraft tend to be much less than for commercial transports because the mass is more evenly distributed along the wing span and they are lifted or plunged vertically during uniform discrete gust encounters with little inertia resistance. Conversely, accelerations in response to discrete gusts tend to be larger than for heavier transports.

**Table 4-1: Rigid body and flexible natural frequencies of all modes used in Discrete Gust Response Analysis.**

Mode no.	Frequency hertz						
1	0	9	4.117058	17	15.33962	25	38.73983
2	0	10	6.115234	18	16.71737	26	40.05799
3	0	11	6.749472	19	21.31522	27	43.87366
4	0.380363	12	8.314463	20	23.91713	28	44.94824
5	0.8129176	13	9.271044	21	26.45134	29	50.46395
6	1.289616	14	10.87025	22	31.49955	30	51.7564
7	2.036124	15	12.84028	23	31.92673	31	55.83799
8	2.201072	16	14.59939	24	36.93553	32	59.57046

The basic model for this analysis is the same semi-span finite element model described in Section 2. The model was structurally constrained to reflect symmetrical motions at the aircraft's centerline. The lowest frequency 32 modes, including three rigid-body modes and 29 flexible modes up to 60 Hertz, were used and are listed in Table 4-1. Mode shapes can be viewed in plots presented in Figure 2.3. The doublet-lattice method was used to compute the unsteady aerodynamics and the box layout used is also the same as in reference Section 1.

The parameters for the single flight condition used in the analysis are listed in Table 4-2. The fuel load, vehicle weight, and pitch inertia conditions specified in the Table are for the full-span aircraft. The weight and pitch inertia was computed from the finite element model. The gust velocity used in the analysis was taken from Reference 1. Some of the dimensions of the Alliance 1 vehicle are given in Table 4-3 and are for the full-span vehicle. The MSC/NASTRAN input file used for the discrete gust response analysis is listed in Appendix H. This file contains the structural and mass element definitions for the half-span finite element model. Since it is an aeroelastic model, the file listing also provides the geometry definitions for doublet lattice unsteady aerodynamics. Because the analysis requires a Fourier transform method to compute time response of the loads and accelerations, the frequency increment and time steps are listed in the Appendix in the FREQ and TSTEP entries. The discrete gust loading is rather complicated, requiring multiple TLOAD2 entries to build a particular excitation waveform for each gust gradient analysis. The TLOAD2 entry is a fairly general waveform generator, but for the purposes of this analysis, it provides unit steps and cosine waveforms. To generate one gust excitation load, multiple TLOAD2 entries are combined with a DLOAD entry to form a 1/2 -cosine/2 waveform shape. To reduce the number of input files, several TLOAD2 and DLOAD sets are listed. Each set represents a different gradient gust case. All the different gradient gust lengths cases are necessary to complete the tuned discrete gust analysis.

Aspect Ratio	24.3
Root Chord	5 ft.
Tip Chord	3.48 ft.

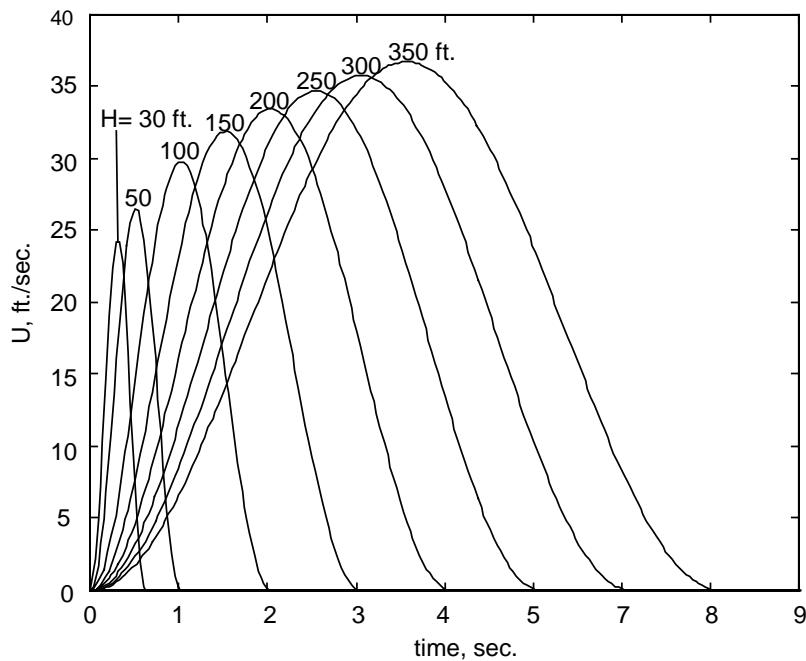

## 4.2 Analysis Procedure

The discrete gust analysis used in SC/NASTRAN is summarized in Figure 4.1, which shows two input paths to generate the gust load time response. The top path generates the prescribed 1-cosine excitation waveform with a peak gust velocity of  $U_{de}$ . The gust velocity waveform is attenuated by the  $H^{1/6}$  factor and converted to a gust angle of attack when it is divided by the vehicle's forward velocity.  $F_g$  has a computed value of nearly one having no effect on this analysis. The final step of the top path is the Fourier transform of the excitation time response into the frequency domain to form an excitation

frequency response function. In the bottom path, the frequency domain equations of motion representing the aeroelastic states and the gust penetration aerodynamics and structural load output coefficients are combined to form the frequency response functions of load output to an arbitrary gust input. Before the unsteady aerodynamics in the aeroelastic equations of motion can be used in the gust analysis, they must first be converted to functions of the real frequencies instead of reduced frequencies. Then the aerodynamics must be interpolated to the gust analysis frequency points (these are the input frequency points listed by FREQ entry). The two paths are combined to form a final product that is a function of frequency. The final product is the load frequency response to the 1-cosine excitation. Each of the load frequency response functions is inverse Fourier transformed to obtain the time history responses of the loads.

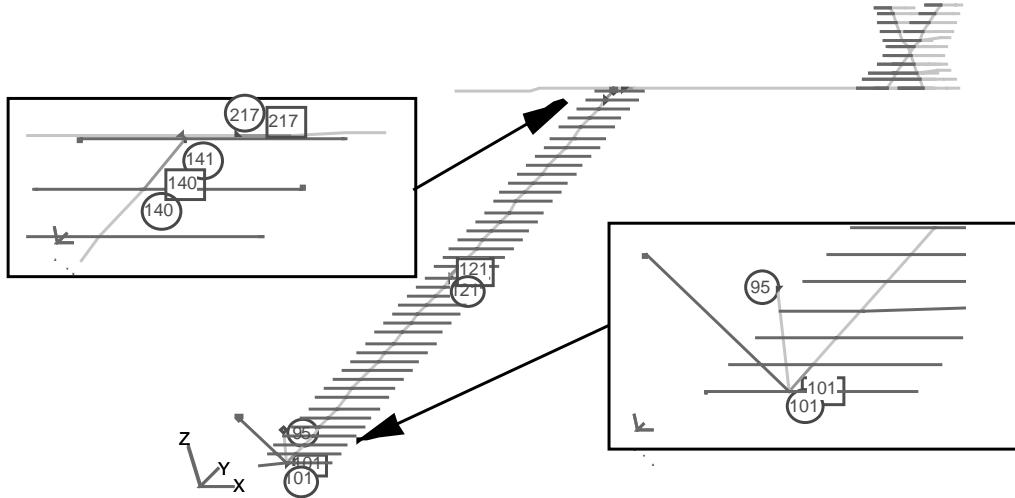

**Figure 4.1: Analysis flow in MSC/NASTRAN for discrete gust response computations.**

**Figure 4.2: The 1 - cosine discrete gust velocities at various gradient lengths.**

Since the MSC/NASTRAN Discrete Gust Response Analysis currently does not have subcase capability to analyze all the different gust gradient lengths for one tuned discrete gust analysis run, it is necessary to run one analysis for each gust gradient length. The velocity waveform plots shown in Figure 4.2 are the velocities computed at point U in the top path of Figure 4.1. The set shown is provided as an example and

is not the one used for this study, but it does show a typical set that would be used to complete a tuned discrete gust analysis of a transport. In order to investigate the maximum structural responses in a light-weight vehicle like the Alliance 1, a special set of gradient lengths was selected which included shorter lengths than for a transport.

**Figure 4.3: Element and node response locations on the half span finite element model of Alliance 1 aircraft.**

### 4.3 Discrete Gust Response Analysis Output Quantities and Locations

For gust load certification purposes, loads and accelerations at many thousands of locations are typically output from a discrete gust response analysis to find the points where critical load conditions can occur on the aircraft. For purposes of this analysis, five points were selected for outputting load and acceleration time history responses. These locations are shown in Figure 4.3 and can be distinguished as nodes or element locations by circles or rectangles around their respective node or element numbers. Many of the locations output both nodal accelerations and element forces. The five location are: node 95 at the CG., node 101 at the centerline and element 101 at wing root, element and node 121 at mid span, element and node 140 at the wing tip, and element and node 217 on the boom just aft of the wing elastic axis. At each of the node locations, in-plane, vertical, and local pitch accelerations are output by MC/NASTRAN. For each bar element location, MSC/NASTRAN outputs in-plane and vertical shear forces, bending moments and torsion moments.

### 4.4 Results and Discussion

Although all the results mentioned above are generated by the MSC/NASTRAN deck in Appendix H, only a selection of the results will be presented in the this report. The wing root location had the largest gust loads. Figures 4.4-4.6 show both the vertical and in-plane components of load. For this location, nearly all the load time responses are shown.

Traditionally, vertical bending moment, vertical shear force, and torsion moment along the wing are computed, since the force created by the gust acts in the vertical direction. The in-plane loads generally are much smaller and regarded as being inconsequential. In this aircraft design, where the wing has a high aspect ratio and the spar consists of round-tube composite construction, the in-plane components of loads are smaller but not inconsequential as compared to the vertical component. In the figures, all the

gust gradient lengths load responses are given as a family of curves. Only one gradient length gives the maximum (or minimum) load for each family of load plots. Table 4-4 lists the gradient lengths used in this tuned gust study and also their respective frequencies. Figure 4.7-Figure 4.9 show a family of the vertical acceleration response curves at the vehicle's wing root, wing mid span, and wing tip locations respectively.

**Table 4-4: Gust gradient lengths and corresponding frequencies used in the tuned gust analysis.**

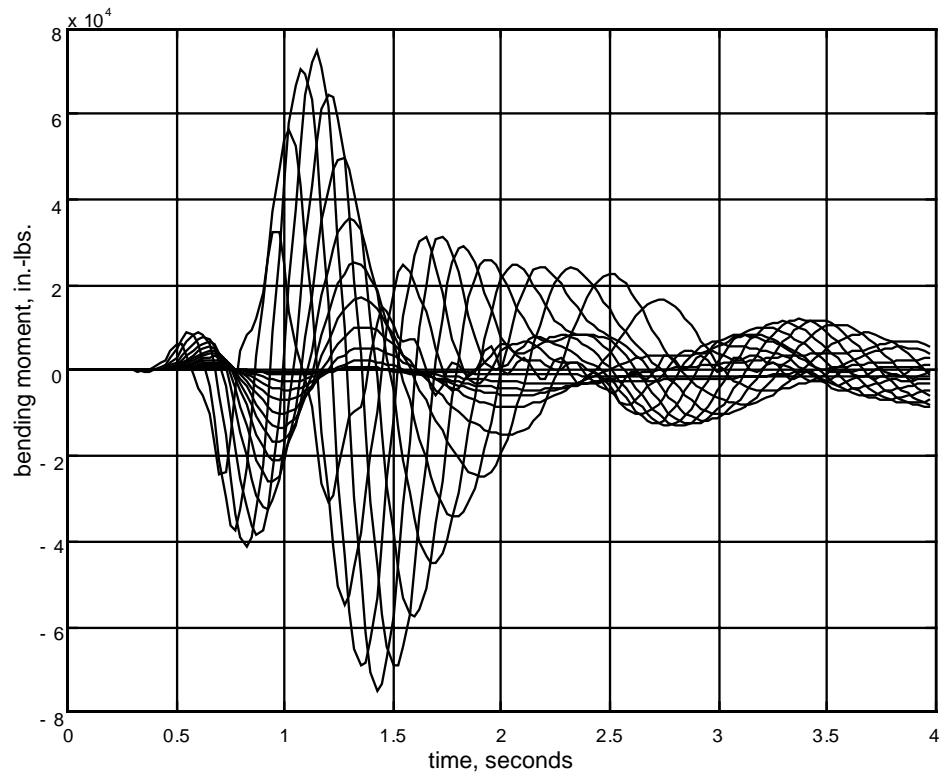

H, ft.	f, hz	H, ft.	f, hz	H, ft.	f, hz
6.64	7.4	39.8	1.23	85.0	.578
13.3	3.7	46.5	1.06	106.	.463
19.9	2.47	53.1	.925	142.	.346
26.6	1.85	60.7	.809	212.	.231
33.2	1.48	70.8	.694	425.	.116

It is interesting to note that the acceleration responses are the largest at mid-span, but if we look at the vehicle in terms of its mass distribution, of the three output locations, mid-span has the least mass. This is expected because the lightest mass areas usually respond with the highest accelerations.

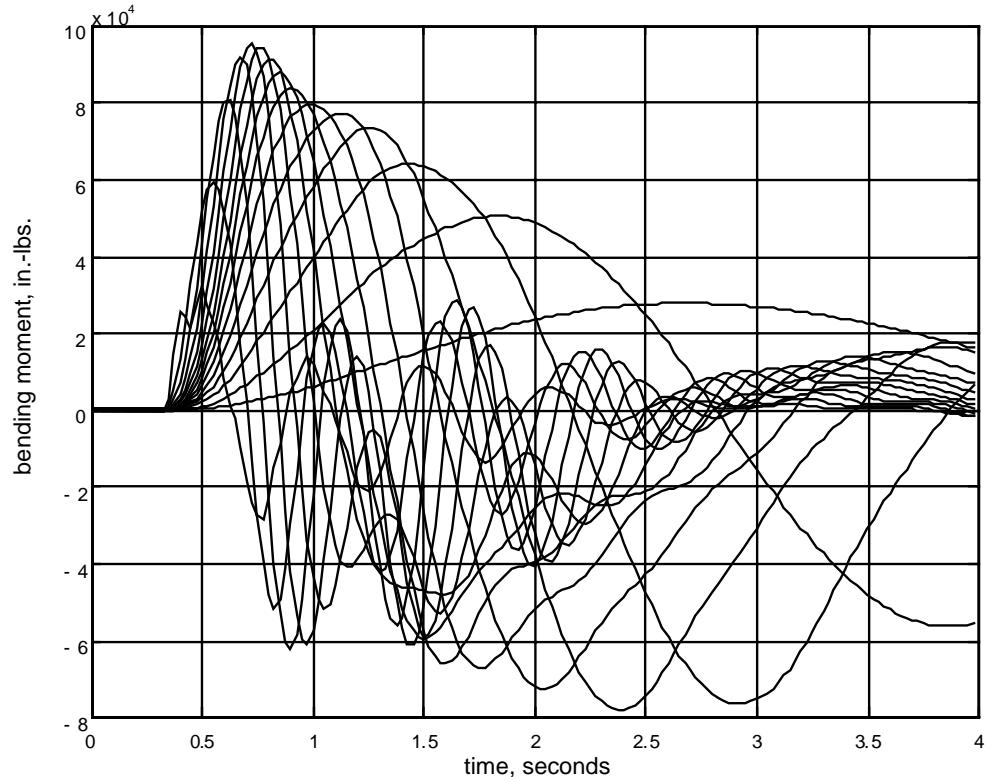

Generally, the response points of highest magnitude are of interest. Figure 4.10-Figure 4.13 show the maximum load and the absolute value of the minimum load for each of the gradient lengths at a given location.

An interesting aspect of this tuned gust analysis is that for all the locations and load types examined, gust gradient lengths of less than 30 feet were needed in order to find the maximum absolute responses. The necessity of using these shorter gradient lengths is significant, since the Federal Aviation Administration Regulation Part 25.341 specifies an analysis range to be between 30 feet to 350 feet. Because the Alliance 1 is very light and exhibits very low natural frequencies, the standard analysis starting point of 30 feet gust gradient length was not low enough. Maximum and minimum accelerations are shown in Figure 4.14-Figure 4.16 . The mid-wing station is shown to attain the highest vertical accelerations of 2.4 g's at a gust gradient length of 13 feet. The frequency of this gradient length is approximately 3 Hertz and it seems to interact with second and third bending modes near 2 to 4 hertz.

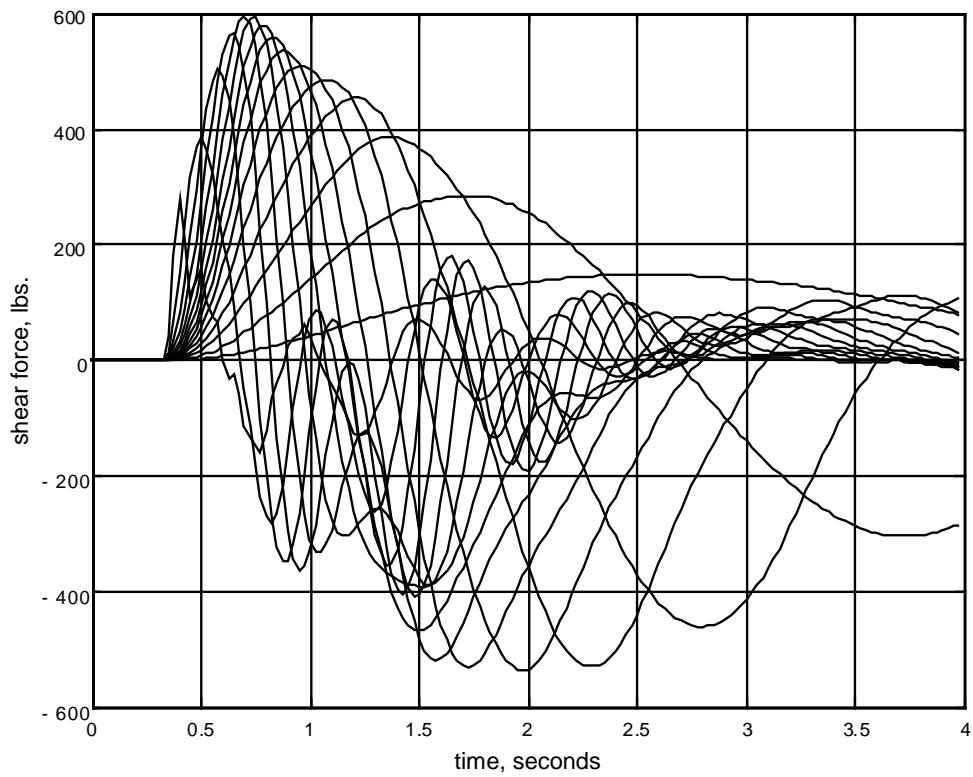

The second and third bending modes show little motion at the wing tip and aircraft centerline, indicating the large mass concentrations at those locations.

13. ABSTRACT (Maximum 200 words)			
<p>This report presents the work performed by Lockheed Martin's Langley Program Office in support of NASA's Environmental Research Aircraft and Sensor Technology (ERAST) program. The primary purpose of this work was to develop and demonstrate a gust analysis method which accounts for the span-wise variation of gust velocity. This is important because these unmanned aircraft having high aspect ratios and low wing loading are very flexible, and fly at low speeds. The main focus of the work was therefore to perform a two-dimensional Power Spectrum Density (PSD) analysis of the Alliance 1 Proof-of-Concept Unmanned Aircraft. As of this writing, none of the aircraft described in this report have been constructed. They are concepts represented by analytical models. The process first involved the development of suitable structural and aeroelastic Finite Element Models (FEM). This was followed by development of a one-dimensional PSD gust analysis, and then the two-dimensional (PSD) analysis of the Alliance 1. For further validation and comparison, two additional analyses were performed. A two-dimensional PSD gust analysis was performed on a simple MSC/NASTRAN example problem. Finally a one-dimensional discrete gust analysis was performed on Alliance 1. This report describes this process, shows the relevant comparisons between analytical methods, and discusses the physical meanings of the results.</p>
